## Equivalence between NFA and DFA

Henrik Nilsson

University of Nottingham

COMP2012/G52LAC/Languages and Computation/Lecture 4 - p.1/8

## Recap: Extended Transition Function

For an NFA, The **Extended Transition Function** is defined on a **set** of states and a **word** (string of symbols).

For a NFA  $A = (Q, \Sigma, \delta, S, F)$ , the extended transition function is defined by:

$$\begin{aligned}\hat{\delta} &\in \mathcal{P}(Q) \times \Sigma^* \rightarrow \mathcal{P}(Q) \\ \hat{\delta}(P, \epsilon) &= P \\ \hat{\delta}(P, xw) &= \hat{\delta}(\bigcup\{\delta(q, x) \mid q \in P\}, w)\end{aligned}$$

where  $P \in \mathcal{P}(Q)$  (or  $P \subseteq Q$ ),  $x \in \Sigma$ ,  $w \in \Sigma^*$ .

COMP2012/G52LAC/Languages and Computation/Lecture 4 - p.4/8

## The Subset Construction (2)

- We can thus **convert** an NFA into a DFA by considering each possible set of NFA states as a single DFA state!

COMP2012/G52LAC/Languages and Computation/Lecture 4 - p.7/8

## Recap: Formal Definition of NFA (1)

Formally, a **Nondeterministic Finite Automaton** or **NFA** is defined by a 5-tuple

$$(Q, \Sigma, \delta, S, F)$$

where

- $Q$  : Finite set of States
- $\Sigma$  : Alphabet (finite set of symbols)
- $\delta \in Q \times \Sigma \rightarrow \mathcal{P}(Q)$  : Transition Function
- $S \subseteq Q$  : Initial States
- $F \subseteq Q$  : Accepting (or Final) States

COMP2012/G52LAC/Languages and Computation/Lecture 4 - p.2/8

## Recap: Language of an NFA

The **language**  $L(A)$  defined by an NFA  $A$  is the set or words **accepted** by the NFA. For an NFA

$$A = (Q, \Sigma, \delta, S, F)$$

the language is defined by

$$L(A) = \{ w \in \Sigma^* \mid \hat{\delta}(S, w) \cap F \neq \emptyset \}$$

COMP2012/G52LAC/Languages and Computation/Lecture 4 - p.5/8

## The Subset Construction (3)

Given an NFA  $A$ :

$$A = (Q, \Sigma, \delta, S, F)$$

we construct the **equivalent** DFA  $D(A)$  as:

$$D(A) = (\mathcal{P}(Q), \Sigma, \delta_{D(A)}, S, F_{D(A)})$$

where

$$\begin{aligned}\delta_{D(A)}(P, x) &= \bigcup\{\delta(q, x) \mid q \in P\} \\ F_{D(A)} &= \{P \in \mathcal{P}(Q) \mid P \cap F \neq \emptyset\}\end{aligned}$$

(Cf. def.  $\hat{\delta}$  and language for NFA!)

COMP2012/G52LAC/Languages and Computation/Lecture 4 - p.8/8

## Recap: Formal Definition of NFA (2)

Note:

- The transition function maps a state and an input symbol to **zero or more** successor states. Thus an NFA has “choice”; hence “nondeterministic”.
- However, nothing ambiguous about the **language** defined by an NFA! **Not** the case that some word  $w \in L(A)$  sometimes, and  $w \notin L(A)$  other times for some NFA  $A$ .
- How? By considering **all possible** states simultaneously.

COMP2012/G52LAC/Languages and Computation/Lecture 4 - p.3/8

## The Subset Construction (1)

Observations:

- An NFA can be in one of a **set** of states.
- When reading an input symbol, the machine enters one of a **new set** of states.
- Which are the **sets** of possible states?
- Each set is a subset of  $Q$ , so the set of possible states is (at most)  $\mathcal{P}(Q)$ .
- But  $Q$  is finite. Thus  $\mathcal{P}(Q)$  is **finite** too!
- There may be **lots** of states as  $|\mathcal{P}(Q)| = 2^{|Q|}$ . But the number of states is finite!
