

# G52MAL Machines and Their Languages Lecture 7

## Minimization of Finite Automata

Henrik Nilsson

University of Nottingham

G52MALMachines and Their LanguagesLecture 7 – p.17

## Applications (2)

- Given two regular expressions  $E$  and  $F$ , check if they denote the same language.

For example, are  $a^*$  and  $(a^*)^*$  equivalent?

One possibility:

$$\text{minimize}(D(N(E))) = \text{minimize}(D(N(F)))$$

where  $=$  is a structural comparison of DFAs.

Not the only or necessarily the best way, but it is one way.

G52MALMachines and Their LanguagesLecture 7 – p.47

## The Table-filling Algorithm (2)

INDUCTION:

For  $p, q, r, s \in Q, a \in \Sigma$ , if

$$(r, s) = (\hat{\delta}(p, a), \hat{\delta}(q, a))$$

a distinguishable state pair, then  $(p, q)$  is also a distinguishable state pair.

Theorem: If two states are **not** distinguishable by the table-filling algorithm, then they are **equivalent**.

G52MALMachines and Their LanguagesLecture 7 – p.77

## Minimization? What and Why?

Q: Is there a unique smallest DFA for recognizing a particular regular language?

- A: - Yes! (Up to renaming of states.)  
- Moreover, this minimal DFA can be found mechanically.

Why useful?

- Small improves efficiency if we want to implement a DFA.
- Unique means it is easy to check if two automata really are the same.

G52MALMachines and Their LanguagesLecture 7 – p.27

## Testing Equivalence of States

For DFA  $(Q, \Sigma, \delta, q_0, F)$ , states  $p, q \in Q$  are **equivalent** iff  $\forall w \in \Sigma^* . \hat{\delta}(p, w) \in F \Leftrightarrow \hat{\delta}(q, w) \in F$

If two states are not equivalent, then they are **distinguishable** on at least one word  $w$ .

Note that an accepting state is always distinguishable from a non-accepting state on the empty word  $\epsilon$ . To see this, assume  $p \in F, q \notin F$ . Then:

$$\begin{aligned}\hat{\delta}(p, \epsilon) &= p \in F \\ \hat{\delta}(q, \epsilon) &= q \notin F\end{aligned}$$

G52MALMachines and Their LanguagesLecture 7 – p.57

## Applications (1)

Applying all we know after this lecture, we can for example:

- Given a regular expression  $E$ , construct the smallest possible DFA for recognizing the language:

$$\text{minimize}(D(N(E)))$$

This is in essence what tools like Lex and Flex do generate efficient scanners from declarative specifications stated in terms of regular expressions.

G52MALMachines and Their LanguagesLecture 7 – p.37

## The Table-filling Algorithm (1)

Systematic discovery of distinguishable state pairs for DFA  $(Q, \Sigma, \delta, q_0, F)$ :

BASIS:

For  $p, q \in Q$ , if

$$(p \in F \wedge q \notin F) \vee (p \notin F \wedge q \in F)$$

then  $(p, q)$  is a distinguishable state pair.
