Software Transactinal Memory

Henrik Nilsson

University of Nottingham, UK

This Lecture

- Some problems with standard approaches to synchronisation
- Software Transactional Memory (STM)
- Haskell used for illustration throughout
- We will also see that STM and pure functional programming is a particularly good match
- We will start with a quick overview of concurrent programming in Haskell.

Concurrent Programming in Haskell

Primitives for concurrent programming provided as operations of the *IO monad*. Excerpts:

forkIO	::	IO () -> IO ThreadId
killThread	::	ThreadId -> IO ()
threadDelay	::	Int -> IO ()
newMVar	::	a -> IO (MVar a)
newEmptyMVar	::	IO (MVar a)
putMVar	::	MVar a -> a -> IO ()
takeMVar	::	MVar a -> IO a

The IO Monad??? (1)

- Haskell uses *monads* as a "bridge" between the pure functional world and the world of input/output, state, and other *effects*.
- For the purpose of this talk, think about a monadic value of type m a as a *computation* in the monad m returning a value of type a described by a sequence of *monadic actions* or "commands".

Software Transactinal Memory - p.1/29

Software Transactinal Memory - p 3/29

The IO Monad??? (2)

- Each monad embodies a particular set of effects.
- Computations may be *composed* into larger computations, but . . .
- ... only when a computation is "*run*" are the actions and their side effects actually carried out.

Key point: *disciplined use of effects*: types account for precisely which effects can occur where.

Concurrency primitives again

Let us revisit the IO concurrency primitives again in the light of what we now know about monads:

forkIO	:: IO () -> IO ThreadId	ł
killThread	:: ThreadId -> IO ()	
threadDelay	:: Int -> IO ()	
newMVar	:: a -> IO (MVar a)	
newEmptyMVar	:: IO (MVar a)	
putMVar	:: MVar a -> a -> IO ()	1
takeMVar	:: MVar a -> IO a	

MVars

- The fundamental synchronisation mechanism is the *MVar* ("em-var").
- An MVar is a "one-item box" that may be *empty* or *full*.
- Reading (takeMVar) and writing (putMVar) are *atomic* operations:
 - Writing to an empty MVar makes it full.
 - Writing to a full MVar blocks.
 - Reading from an empty MVar blocks.
 - Reading from a full MVar makes it empty.

Example: Basic Synchronization (1)

module Main where

import Control.Concurrent

```
countFromTo :: Int -> Int -> IO ()
countFromTo m n
```

```
| m > n = return ()
| otherwise = do
    putStrLn (show m)
    countFromTo (m+1) n
```

Software Transactinal Memory – p.6/29

Software Transactinal Memory - p.5/29

Software Transactinal Memory - p 7/29

Example: Basic Synchronization (2)

```
main = do
start <- newEmptyMVar
done <- newEmptyMVar
forkIO $ do
        takeMVar start
        countFromTo 1 10
        putMVar done ()
putStrLn "Go!"
putMVar start ()
takeMVar done
(countFromTo 11 20)
putStrLn "Done!"</pre>
```

Example: Unbounded Buffer (1)

module Main where

```
import Control.Monad (when)
import Control.Concurrent
```

```
newtype Buffer a =
    Buffer (MVar (Either [a] (Int, MVar a)))
```

```
return (Buffer b)
```

Software Transactinal Memory – p.10/29

Software Transactinal Memory - p.9/29

Example: Unbounded Buffer (2)

```
readBuffer :: Buffer a -> IO a
readBuffer (Buffer b) = do
    bc <- takeMVar b
    case bc of
      Left (x : xs) -> do
        putMVar b (Left xs)
        return x
    Left [] -> do
        w <- newEmptyMVar
        putMVar b (Right (1,w))
        takeMVar w
    Right (n,w) -> do
        putMVar b (Right (n + 1, w))
        takeMVar w
```

Example: Unbounded Buffer (3)

Why isn't Buffer simply defined as

newtype Buffer a = Buffer [a]

?

Hint: What would happen if e.g. an attempt is made to read from an empty buffer?

Software Transactinal Memory - p 11/29

Example: Unbounded Buffer (4)

```
writeBuffer :: Buffer a -> a -> IO ()
writeBuffer (Buffer b) x = do
    bc <- takeMVar b
    case bc of
      Left xs ->
        putMVar b (Left (xs ++ [x]))
    Right (n,w) -> do
      putMVar w x
      if n > 1 then
        putMVar b (Right (n - 1, w))
      else
        putMVar b (Left [])
```

Example: Unbounded Buffer (5)

The buffer can now be used as a channel of communication between a set of "writers" and a set of "readers". E.g.

```
main = do
```

```
b <- newBuffer</pre>
```

- forkIO (writer b)
- forkIO (writer b)
- forkIO (reader b)

```
forkIO (reader b)
```

```
• • •
```

Example: Unbounded Buffer (6)

```
reader :: Buffer Int -> IO ()
reader n b = rLoop
where
    rLoop = do
        x <- readBuffer b
        when (x > 0) $ do
            putStrLn (n ++ ": " ++ show x)
            rLoop
```

Compositionality? (1)

Suppose we would like to read two *consecutive* elements from a buffer b?

That is, sequential composition.

Would the following work?

x1 <- readBuffer b

x2 <- readBuffer b

Software Transactinal Memory - p 15/29

Compositionality? (2)

What about this?

```
mutex <- newMVar ()
...
takeMVar mutex
x1 <- readBuffer b
x2 <- readBuffer b
putMVar mutex ()</pre>
```

Compositionality? (3)

Suppose we would like to read from *one of two* buffers.

Software Transactinal Memory - p.17/29

Software Transactinal Memory – p.18/29

That is, composing alternatives.

Hmmm. How do we even begin?

- No way to attempt reading a buffer without risking blocking.
- We have to change or enrich the buffer implementation. E.g. add a tryReadBuffer operation, and then repeatedly poll the two buffers in a tight loop. Not so good!

Software Transactional Memory (1)

- Operations on shared mutable variables grouped into *transactions*.
- A transaction either succeeds or fails in its entirety. I.e., atomic w.r.t. other transactions.
- Failed transactions are automatically *retried* until they succeed.
- **Transaction logs**, which records reading and writing of shared variables, maintained to enable transactions to be validated, partial transactions to be rolled back, and to determine when worth trying a transaction again.

Software Transactional Memory (2)

• No locks! (At the application level.)

Software Transactinal Memory - p.19/29

STM and Pure Declarative Languages

- STM perfect match for *purely declarative languages*:
 - reading and writing of shared mutable variables explicit and relatively rare;
 - most computations are pure and need not be logged.
- Disciplined use of effects through monads a huge payoff: easy to ensure that only effects that can be undone can go inside a transaction.

(Imagine the havoc arbitrary I/O actions could cause if part of transaction: How to undo? What if retried?)

The STM monad

The software transactional memory abstraction provided by a monad STM. *Distinct from IO!* Defined in Control.Concurrent.STM.

Excerpts:

```
newTVar :: a -> STM (TVar a)
writeTVar :: TVar a -> a -> STM ()
readTVar :: TVar a -> STM a
retry :: STM a
atomically :: STM a -> IO a
```

Example: Buffer Revisited (1)

Let us rewrite the unbounded buffer using the STM monad: module Main where

import Control.Monad (when)
import Control.Concurrent
import Control.Concurrent.STM

newtype Buffer a = Buffer (TVar [a])

```
newBuffer :: STM (Buffer a)
newBuffer = do
            b <- newTVar []
            return (Buffer b)</pre>
```

Example: Buffer Revisited (2)

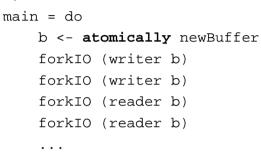

```
readBuffer :: Buffer a -> STM a
readBuffer (Buffer b) = do
    xs <- readTVar b
    case xs of
    []         -> retry
    (x : xs') -> do
        writeTVar b xs'
        return x
writeBuffer :: Buffer a -> a -> STM ()
writeBuffer (Buffer b) x = do
    xs <- readTVar b
    writeTVar b (xs ++ [x])</pre>
```

Software Transactinal Memory - p. 21/29

Software Transactinal Memory - p 23/29

Example: Buffer Revisited (3)

The main program and code for readers and writers can remain unchanged, except that STM operations must be carried out *atomically*:

Example: Buffer Revisited (4)

```
reader :: Buffer Int -> IO ()
reader n b = rLoop
where
    rLoop = do
        x <- atomically (readBuffer b)
        when (x > 0) $ do
            putStrLn (n ++ ": " ++ show x)
            rLoop
Why shouldn't atomically be part of the
definition of readBuffer?
```

Composition (1)

STM operations can be *robustly composed*. That's the reason for making readBuffer and writeBuffer STM operations, and leaving it to client code to decide the scope of atomic blocks.

Example, sequential composition: reading two consecutive elements from a buffer b:

atomically \$ do x1 <- readBuffer b x2 <- readBuffer b ...

Composition (2)

Example, composing alternatives: reading from one of two buffers b1 and b2:

```
x <- atomically $
    readBuffer b1
    `orElse` readBuffer b2</pre>
```

The buffer operations thus composes nicely. No need to change the implementation of any of the operations!
