

# MGS 2007: ADV Lecture 3

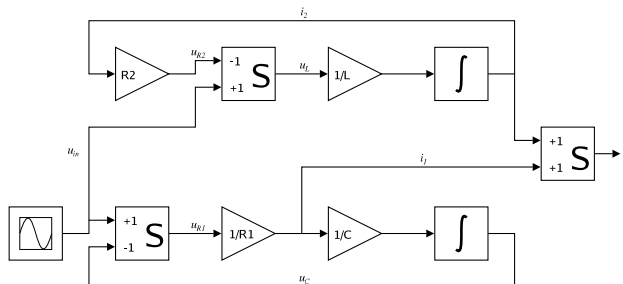

## Arrows and Functional Reactive Programming

Henrik Nilsson

University of Nottingham, UK

## Arrows (2)

But systems can be complex:

**How many and what combinators do we need to be able to describe arbitrary systems?**

## Arrows (1)

System descriptions in the form of block diagrams are very common. Blocks have inputs and outputs and can be combined into larger blocks. For example, serial composition:

A *combinator* can be defined that captures this idea:

$$(>>>) :: B \ a \ b \ -> \ B \ b \ c \ -> \ B \ a \ c$$

## Arrows (3)

John Hughes' **arrow** framework:

- Abstract data type interface for function-like types (or “blocks”, if you prefer).
- Particularly suitable for types representing process-like computations.
- Related to **monads**, since arrows are computations, but more general.
- Provides a minimal set of “wiring” combinators.

## What is an arrow? (1)

- A **type constructor**  $a$  of arity two.
- Three operators:
  - **lifting**:  
 $\text{arr} :: (b \rightarrow c) \rightarrow a \ b \ c$
  - **composition**:  
 $(\ggg) :: a \ b \ c \rightarrow a \ c \ d \rightarrow a \ b \ d$
  - **widening**:  
 $\text{first} :: a \ b \ c \rightarrow a \ (b,d) \ (c,d)$
- A set of **algebraic laws** that must hold.

MGS 2007: ADV Lecture 3 – p.5/46

## The Arrow class

In Haskell, a **type class** is used to capture these ideas (except for the laws):

```
class Arrow a where
  arr    :: (b -> c) -> a b c
  (>>>) :: a b c -> a c d -> a b d
  first  :: a b c -> a (b,d) (c,d)
```

MGS 2007: ADV Lecture 3 – p.7/46

## What is an arrow? (2)

These diagrams convey the general idea:

MGS 2007: ADV Lecture 3 – p.6/46

## Functions are arrows (1)

Functions are a simple example of arrows, with  $(\rightarrow)$  as the arrow type constructor.

**Exercise 1:** Suggest suitable definitions of

- $\text{arr}$
- $(\ggg)$
- $\text{first}$

for this case!

(We have not looked at what the laws are yet, but they are “natural”.)

MGS 2007: ADV Lecture 3 – p.8/46

## Functions are arrows (2)

Solution:

- `arr = id`

To see this, recall

`id :: t -> t`

`arr :: (b->c) -> a b c`

Instantiate with

`a = (->)`

`t = b->c = (->) b c`

MGS 2007: ADV Lecture 3 – p.9/46

## Functions are arrows (4)

Arrow instance declaration for functions:

`instance Arrow (->) where`

`arr = id`

`(>>>) = flip (.)`

`first f = \ (b,d) -> (f b,d)`

MGS 2007: ADV Lecture 3 – p.11/46

## Functions are arrows (3)

- `f >>> g = \a -> g (f a)` **or**
- `f >>> g = g . f` **or even**
- `(>>>) = flip (.)`
- `first f = \ (b,d) -> (f b,d)`

MGS 2007: ADV Lecture 3 – p.10/46

## Some arrow laws

`(f >>> g) >>> h = f >>> (g >>> h)`

`arr (f >>> g) = arr f >>> arr g`

`arr id >>> f = f`

`f = f >>> arr id`

`first (arr f) = arr (first f)`

`first (f >>> g) = first f >>> first g`

**Exercise 2:** Draw diagrams illustrating the first and last law!

MGS 2007: ADV Lecture 3 – p.12/46

## The loop combinator (1)

Another important operator is `loop`: a fixed-point operator used to express recursive arrows or **feedback**:

MGS 2007: ADV Lecture 3 – p.13/46

## Some more arrow combinators (1)

`second` :: Arrow a =>  
 $a\ b\ c \rightarrow a\ (d,b)\ (d,c)$

`(***)` :: Arrow a =>  
 $a\ b\ c \rightarrow a\ d\ e \rightarrow a\ (b,d)\ (c,e)$

`(&&&)` :: Arrow a =>  
 $a\ b\ c \rightarrow a\ b\ d \rightarrow a\ b\ (c,d)$

MGS 2007: ADV Lecture 3 – p.15/46

## The loop combinator (2)

Not all arrow instances support `loop`. It is thus a method of a separate class:

```
class Arrow a => ArrowLoop a where
    loop :: a (b, d) (c, d) -> a b c
```

Remarkably, the four combinators `arr`, `>>>`, `first`, and `loop` are sufficient to express any conceivable wiring!

MGS 2007: ADV Lecture 3 – p.14/46

## Some more arrow combinators (2)

As diagrams:

MGS 2007: ADV Lecture 3 – p.16/46

## Some more arrow combinators (3)

```
second :: Arrow a => a b c -> a (d,b) (d,c)
second f = arr swap >>> first f >>> arr swap
swap (x,y) = (y,x)
```

```
(***) :: Arrow a =>
  a b c -> a d e -> a (b,d) (c,e)
f *** g = first f >>> second g
```

```
(&&&) :: Arrow a => a b c -> a b d -> a b (c,d)
f &&& g = arr (\x->(x,x)) >>> (f *** g)
```

MGS 2007: ADV Lecture 3 – p.17/46

## Exercise 3: One solution

**Exercise 3:** Describe the following circuit using arrow combinators:

$a_1, a_2, a_3 :: A \text{ Double Double}$

```
circuit_v1 :: A Double Double
circuit_v1 = (a1 &&& arr id)
  >>> (a2 *** a3)
  >>> arr (uncurry (+))
```

MGS 2007: ADV Lecture 3 – p.19/46

## Exercise 3

Describe the following circuit using arrow combinators:

$a_1, a_2, a_3 :: A \text{ Double Double}$

MGS 2007: ADV Lecture 3 – p.18/46

## Exercise 3: Another solution

**Exercise 3:** Describe the following circuit:

$a_1, a_2, a_3 :: A \text{ Double Double}$

```
circuit_v2 :: A Double Double
circuit_v2 = arr (\x -> (x,x))
  >>> first a1
  >>> (a2 *** a3)
  >>> arr (uncurry (+))
```

MGS 2007: ADV Lecture 3 – p.20/46

## Note on the definition of (`***`) (1)

Are the following two definitions of (`***`) equivalent?

- `f *** g = first f >>> second g`
- `f *** g = second g >>> first f`

No, in general

`first f >>> second g`  $\neq$  `second g >>> first f`

since the **order** of the two possibly effectful computations `f` and `g` are different.

MGS 2007: ADV Lecture 3 – p.21/46

## Yet an attempt at exercise 3

```
circuit_v3 :: A Double Double
circuit_v3 = (a1 &&& a3)
            >>> first a2
            >>> arr (uncurry (+))
```

**Exercise 4:** Are `circuit_v1`, `circuit_v2`, and `circuit_v3` all equivalent?

MGS 2007: ADV Lecture 3 – p.23/46

## Note on the definition of (`***`) (2)

Similarly

$(f *** g) >>> (h *** k) \neq (f >>> h) *** (g >>> k)$

since the order of `f` and `g` differs.

However, the following **is** true (an additional law):

$$\begin{aligned} & \text{first } f >>> \text{second (arr } g) \\ & = \text{second (arr } g) >>> \text{first } f \end{aligned}$$

However, for certain **arrow instances** equalities like the ones above do hold.

MGS 2007: ADV Lecture 3 – p.22/46

## The arrow `do` notation (1)

Ross Paterson's `do`-notation for arrows supports **pointed** arrow programming. Only **syntactic sugar**.

```
proc pat -> do [ rec ]
  pat1 <- sfexp1 -< exp1
  pat2 <- sfexp2 -< exp2
  ...
  patn <- sfexpn -< expn
  returnA -< exp
```

Also: `let pat = exp`  $\equiv$  `pat <- arr id -< exp`

MGS 2007: ADV Lecture 3 – p.24/46

## The arrow do notation (2)

Let us redo exercise 3 using this notation:

```
circuit_v4 :: A Double Double
circuit_v4 = proc x -> do
  y1 <- a1 -< x
  y2 <- a2 -< y1
  y3 <- a3 -< x
  returnA -< y2 + y3
```

MGS 2007: ADV Lecture 3 – p.25/46

## The arrow do notation (3)

We can also mix and match:

```
circuit_v5 :: A Double Double
circuit_v5 = proc x -> do
  y2 <- a2 <<< a1 -< x
  y3 <- a3 -< x
  returnA -< y2 + y3
```

MGS 2007: ADV Lecture 3 – p.26/46

## The arrow do notation (4)

Recursive networks: do-notation:

```
a1, a2 :: A Double Double
a3 :: A (Double, Double) Double
```

**Exercise 5:** Describe this using only the arrow combinators.

MGS 2007: ADV Lecture 3 – p.27/46

## The arrow do notation (5)

```
circuit = proc x -> do
  rec
  y1 <- a1 -< x
  y2 <- a2 -< y1
  y3 <- a3 -< (x, y)
  let y = y2 + y3
  returnA -< y
```

MGS 2007: ADV Lecture 3 – p.28/46

## Arrows and Monads (1)

Arrows generalize monads: for every monad type there is an arrow, the **Kleisli category** for the monad:

```
newtype Kleisli m a b = K (a -> m b)

instance Monad m => Arrow (Kleisli m) where
  arr f      = K (\b -> return (f b))
  K f >>> K g = K (\b -> f b >>= g)
```

MGS 2007: ADV Lecture 3 – p.29/46

## An application: FRP

Functional Reactive Programming (FRP):

- Paradigm for **reactive programming** in a functional setting:
  - Input arrives **incrementally** while system is running.
  - Output is generated in response to input in an interleaved and **timely** fashion.
- Originated from Functional Reactive Animation (Fran) (Elliott & Hudak).
- Has evolved in a number of directions and into different concrete implementations.

MGS 2007: ADV Lecture 3 – p.31/46

## Arrows and Monads (2)

But not every arrow is a monad. However, arrows that support an additional `apply` operation **are** effectively monads:

```
apply :: Arrow a => a (a b c, b) c
```

Exercise 6: Verify that

```
newtype M b = M (A () b)
```

is a monad if `A` is an arrow supporting `apply`; i.e., define `return` and `bind` in terms of the arrow operations (and verify that the monad laws hold).

MGS 2007: ADV Lecture 3 – p.30/46

## Yampa

**Yampa:**

- The most recent Yale FRP implementation.
- **Embedding** in Haskell (a Haskell library).
- **Arrows** used as the basic structuring framework.
- **Continuous time.**
- Discrete-time signals modelled by continuous-time signals and an option type.
- Advanced **switching constructs** allows for highly dynamic system structure.

MGS 2007: ADV Lecture 3 – p.32/46

## Related languages

FRP related to:

- Synchronous languages, like Esterel, Lucid Synchrone.
- Modeling languages, like Simulink.

Distinguishing features of FRP:

- First class reactive components.
- Allows highly dynamic system structure.
- Supports hybrid (mixed continuous and discrete) systems.

MGS 2007: ADV Lecture 3 – p.33/46

## Yampa?

Yampa is a river with long calmly flowing sections and abrupt whitewater transitions in between.

A good metaphor for hybrid systems!

MGS 2007: ADV Lecture 3 – p.35/46

## FRP applications

Some domains where FRP has been used:

- Graphical Animation (Fran: Elliott, Hudak)
- Robotics (Frob: Peterson, Hager, Hudak, Elliott, Pembeci, Nilsson)
- Vision (FVision: Peterson, Hudak, Reid, Hager)
- GUIs (Fruit: Courtney)
- Hybrid modeling (Nilsson, Hudak, Peterson)

MGS 2007: ADV Lecture 3 – p.34/46

## Signal functions

Key concept: **functions on signals**.

Intuition:

Signal  $\alpha \approx \text{Time} \rightarrow \alpha$

$x :: \text{Signal } T1$

$y :: \text{Signal } T2$

SF  $\alpha \beta \approx \text{Signal } \alpha \rightarrow \text{Signal } \beta$

$f :: \text{SF } T1 \ T2$

Additionally: **causality** requirement.

MGS 2007: ADV Lecture 3 – p.36/46

## Signal functions and state

Alternative view:

Signal functions can encapsulate **state**.

$state(t)$  summarizes input history  $x(t')$ ,  $t' \in [0, t]$ .

Functions on signals are either:

- **Stateful**:  $y(t)$  depends on  $x(t)$  and  $state(t)$
- **Stateless**:  $y(t)$  depends only on  $x(t)$

MGS 2007: ADV Lecture 3 – p.37/46

## Some further basic signal functions

- `identity :: SF a a`  
`identity = arr id`
- `constant :: b -> SF a b`  
`constant b = arr (const b)`
- `integral :: VectorSpace a s => SF a a`
- `time :: SF a Time`  
`time = constant 1.0 >>> integral`
- `(^<<) :: (b->c) -> SF a b -> SF a c`  
`f (^<<) sf = sf >>> arr f`

MGS 2007: ADV Lecture 3 – p.39/46

## Yampa and Arrows

SF is an arrow. Signal function instances of core combinators:

- `arr :: (a -> b) -> SF a b`
- `>>> :: SF a b -> SF b c -> SF a c`
- `first :: SF a b -> SF (a,c) (b,c)`
- `loop :: SF (a,c) (b,c) -> SF a b`

But `apply` has no useful meaning. Hence SF is **not a monad**.

MGS 2007: ADV Lecture 3 – p.38/46

## Example: A bouncing ball

$$y = y_0 + \int v dt$$

$$v = v_0 + \int -9.81$$

On impact:

$$v = -v(t-)$$

(fully elastic collision)

MGS 2007: ADV Lecture 3 – p.40/46

## Part of a model of the bouncing ball

Free-falling ball:

```
type Pos = Double
type Vel = Double
```

```
fallingBall ::
  Pos -> Vel -> SF () (Pos, Vel)
fallingBall y0 v0 = proc () -> do
  v <- (v0 +) ^<< integral -< -9.81
  y <- (y0 +) ^<< integral -< v
  returnA -< (y, v)
```

MGS 2007: ADV Lecture 3 – p.41/46

## Example: Space Invaders

MGS 2007: ADV Lecture 3 – p.43/46

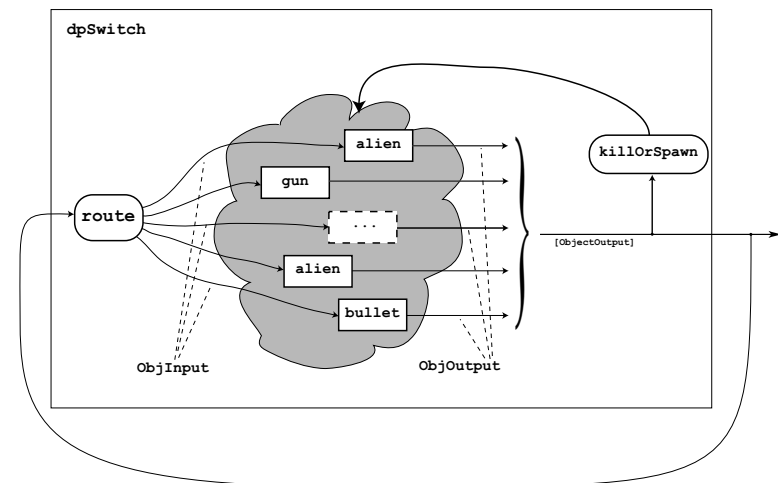

## Dynamic system structure

**Switching** allows the structure of the system to evolve over time:

MGS 2007: ADV Lecture 3 – p.42/46

## Overall game structure

MGS 2007: ADV Lecture 3 – p.44/46
