

# REVIEW OF HASKELL

A lightening tour in 45 minutes

# What is a Functional Language?

Opinions differ, and it is difficult to give a precise definition, but generally speaking:

- Functional programming is style of programming in which the basic method of computation is the application of functions to arguments;
- A functional language is one that supports and encourages the functional style.

# Example

Summing the integers 1 to 10 in Java:

```
total = 0;  
for (i = 1; i ≤ 10; ++i)  
    total = total+i;
```

The computation method is variable assignment.

# Example

Summing the integers 1 to 10 in Haskell:

```
sum [1..10]
```

The computation method is function application.

# This Lecture

A series of six micro-lectures on Haskell:

- First steps;
- Types in Haskell;
- Defining functions;
- List comprehensions;
- Recursive functions;
- Declaring types.

# REVIEW OF HASKELL

## 1 - First Steps

# Glasgow Haskell Compiler

- GHC is the leading implementation of Haskell, and comprises a compiler and interpreter;
- The interactive nature of the interpreter makes it well suited for teaching and prototyping;
- GHC is freely available from:

[www.haskell.org/platform](http://www.haskell.org/platform)

# Starting GHC

The GHC interpreter can be started from the Unix command prompt % by simply typing ghci:

```
% ghci
```

```
GHCi, version 8.0.1: http://www.haskell.org/ghc/ :? for help
```

```
Prelude>
```

The GHCi prompt `>` means that the interpreter is ready to evaluate an expression.

For example:

```
> 2+3*4
```

```
14
```

```
> (2+3)*4
```

```
20
```

```
> sqrt (3^2 + 4^2)
```

```
5.0
```

# Function Application

In mathematics, function application is denoted using parentheses, and multiplication is often denoted using juxtaposition or space.

$$f(a, b) + c d$$

Apply the function  $f$  to  $a$  and  $b$ , and add the result to the product of  $c$  and  $d$ .

In Haskell, function application is denoted using space, and multiplication is denoted using `*`.

```
f a b + c*d
```

As previously, but in Haskell syntax.

Moreover, function application is assumed to have higher priority than all other operators.

f a + b

Means  $(f\ a) + b$ , rather than  $f\ (a + b)$ .

# REVIEW OF HASKELL

## 2 - Types in Haskell

# What is a Type?

A type is a name for a collection of related values.  
For example, in Haskell the basic type

Bool

contains the two logical values:

False

True

# Types in Haskell

- If evaluating an expression  $e$  would produce a value of type  $t$ , then  $e$  has type  $t$ , written

$e :: t$

- Every well formed expression has a type, which can be automatically calculated at compile time using a process called type inference.

# Basic Types

Haskell has a number of basic types, including:

Bool

- logical values

Char

- single characters

String

- strings of characters

Int

- fixed-precision integers

# List Types

A list is sequence of values of the same type:

```
[False, True, False] :: [Bool]
```

```
['a', 'b', 'c', 'd'] :: [Char]
```

In general:

[t] is the type of lists with elements of type t.

# Tuple Types

A tuple is a sequence of values of different types:

```
(False, True)      :: (Bool, Bool)
```

```
(False, 'a', True) :: (Bool, Char, Bool)
```

In general:

$(t_1, t_2, \dots, t_n)$  is the type of  $n$ -tuples whose  $i$ th components have type  $t_i$  for any  $i$  in  $1 \dots n$ .

# Function Types

A function is a mapping from values of one type to values of another type:

```
not      :: Bool → Bool
```

```
isDigit :: Char → Bool
```

In general:

$t_1 \rightarrow t_2$  is the type of functions that map values of type  $t_1$  to values to type  $t_2$ .

# Polymorphic Functions

A function is called polymorphic (“of many forms”) if its type contains one or more type variables.

```
length :: [a] → Int
```

for any type  $a$ , `length` takes a list of values of type  $a$  and returns an integer.

# REVIEW OF HASKELL

## 3 - Defining Functions

# Conditional Expressions

As in most programming languages, functions can be defined using conditional expressions.

```
abs  :: Int → Int  
abs n = if n ≥ 0 then n else -n
```

abs takes an integer  $n$  and returns  $n$  if it is non-negative and  $-n$  otherwise.

# Pattern Matching

Many functions have a particularly clear definition using pattern matching on their arguments.

```
not      :: Bool → Bool
not False = True
not True  = False
```

not maps False to True, and True to False.

# List Patterns

Internally, every non-empty list is constructed by repeated use of an operator (`:`) called “cons” that adds an element to the start of a list.

[1, 2, 3, 4]

Means `1:(2:(3:(4:[])))`.

Functions on lists can be defined using  $x:xs$  patterns.

```
head      :: [a] → a
head (x:_) = x

tail      :: [a] → [a]
tail (_:xs) = xs
```

head and tail map any non-empty list to its first and remaining elements.

# Lambda Expressions

A function can be constructed without giving it a name by using a lambda expression.

$\lambda x \rightarrow x+1$

The nameless function that takes a number  $x$  and returns the result  $x+1$ .

# Why Are Lambda's Useful?

Lambda expressions can be used to give a formal meaning to functions defined using currying.

For example:

```
add x y = x+y
```

means

```
add =  $\lambda x \rightarrow (\lambda y \rightarrow x+y)$ 
```

# REVIEW OF HASKELL

## 4 - List Comprehensions

# Lists Comprehensions

In Haskell, the comprehension notation can be used to construct new lists from old lists.

```
[x^2 | x ← [1..5]]
```

The list [1,4,9,16,25] of all numbers  $x^2$  such that  $x$  is an element of the list [1..5].

## Note:

- The expression  $x \leftarrow [1..5]$  is called a generator, as it states how to generate values for  $x$ .
- Comprehensions can have multiple generators, separated by commas. For example:

```
> [(x,y) | x ← [1,2,3], y ← [4,5]]  
[(1,4), (1,5), (2,4), (2,5), (3,4), (3,5)]
```

# Dependant Generators

Later generators can depend on the variables that are introduced by earlier generators.

```
[(x,y) | x ← [1..3], y ← [x..3]]
```

The list  $[(1,1),(1,2),(1,3),(2,2),(2,3),(3,3)]$  of all pairs of numbers  $(x,y)$  such that  $x,y$  are elements of the list  $[1..3]$  and  $y \geq x$ .

Using a dependant generator we can define the library function that concatenates a list of lists:

```
concat    :: [[a]] → [a]
concat xss = [x | xs ← xss, x ← xs]
```

For example:

```
> concat [[1,2,3],[4,5],[6]]
[1,2,3,4,5,6]
```

# Guards

List comprehensions can use guards to restrict the values produced by earlier generators.

```
[x | x ← [1..10], even x]
```

The list `[2,4,6,8,10]` of all numbers `x` such that `x` is an element of the list `[1..10]` and `x` is even.

Using a guard we can define a function that maps a positive integer to its list of factors:

```
factors  :: Int → [Int]
factors n =
    [x | x ← [1..n], n `mod` x == 0]
```

For example:

```
> factors 15
[1, 3, 5, 15]
```

# REVIEW OF HASKELL

## 5 - Recursive Functions

# Recursive Functions

In Haskell, functions can also be defined in terms of themselves. Such functions are called recursive.

```
factorial 0 = 1  
factorial n = n * factorial (n-1)
```

factorial maps 0 to 1, and any other integer to the product of itself and the factorial of its predecessor.

For example:

$$\begin{aligned} & \text{factorial } 3 \\ = & 3 * \text{factorial } 2 \\ = & 3 * (2 * \text{factorial } 1) \\ = & 3 * (2 * (1 * \text{factorial } 0)) \\ = & 3 * (2 * (1 * 1)) \\ = & 3 * (2 * 1) \\ = & 3 * 2 \\ = & 6 \end{aligned}$$

# Why is Recursion Useful?

- Some functions, such as factorial, are simpler to define in terms of other functions.
- As we shall see, however, many functions can naturally be defined in terms of themselves.
- Properties of functions defined using recursion can be proved using the simple but powerful mathematical technique of induction.

# Recursion on Lists

Recursion is not restricted to numbers, but can also be used to define functions on lists.

```
product      :: [Int] → Int
product []   = 1
product (n:ns) = n * product ns
```

product maps the empty list to 1,  
and any non-empty list to its head  
multiplied by the product of its tail.

For example:

```
product [2,3,4]
=
2 * product [3,4]
=
2 * (3 * product [4])
=
2 * (3 * (4 * product []))
=
2 * (3 * (4 * 1))
=
24
```

# REVIEW OF HASKELL

## 6 - Declaring Types

# Data Declarations

A new type can be declared by specifying its set of values using a data declaration.

```
data Bool = False | True
```

Bool is a new type, with two new values False and True.

Values of new types can be used in the same ways as those of built in types. For example, given

```
data Answer = Yes | No | Unknown
```

we can define:

```
answers      :: [Answer]
answers      = [Yes, No, Unknown]

flip         :: Answer → Answer
flip Yes    = No
flip No     = Yes
flip Unknown = Unknown
```

# Recursive Types

In Haskell, new types can be declared in terms of themselves. That is, types can be recursive.

```
data Nat = Zero | Succ Nat
```

Nat is a new type, with constructors  
 $\text{Zero} :: \text{Nat}$  and  $\text{Succ} :: \text{Nat} \rightarrow \text{Nat}$ .

## Note:

- A value of type `Nat` is either `Zero`, or of the form `Succ n` where  $n :: \text{Nat}$ . That is, `Nat` contains the following infinite sequence of values:

`Zero`

`Succ Zero`

`Succ (Succ Zero)`

⋮

Using recursion, it is easy to define functions that convert between values of type Nat and Int:

```
nat2int      :: Nat → Int
nat2int Zero  = 0
nat2int (Succ n) = 1 + nat2int n

int2nat      :: Int → Nat
int2nat 0     = Zero
int2nat n     = Succ (int2nat (n-1))
```

Two naturals can be added by converting them to integers, adding, and then converting back:

```
add    :: Nat → Nat → Nat
add m n = int2nat (nat2int m + nat2int n)
```

However, using recursion the function `add` can be defined without the need for conversions:

```
add Zero    n = n
add (Succ m) n = Succ (add m n)
```
