Regular Expressions

Henrik Nilsson

University of Nottingham

COMP2012/G52LAC/Languages and Computation/Lecture 5 - p.17

Regular Expressions

- Automata describe languages in a somewhat indirect way: not always obvious what the defined language is.
- **Regular Expressions** offer a different, more direct way to describe languages.
- We will see (later) that the class of languages that can be described by regular expressions again is the same as those describable by DFAs and NFAs.
- This class is called the **regular** languages. Hence the name regular expressions.

COMP2012/G52LAC/Languages and Computation/Lecture 5 - p.47

Semantics of Regular Expressions

1. $L(\emptyset) = \emptyset$
2. $L(\epsilon) = \{\epsilon\}$
3. For all $x \in \Sigma$, $L(x) = \{x\}$
4. $L(E + F) = L(E) \cup L(F)$
5. $L(EF) = L(E)L(F)$
6. $L(E^*) = L(E)^*$
7. $L((E)) = L(E)$

COMP2012/G52LAC/Languages and Computation/Lecture 5 - p.77

Recap: DFAs and NFAs (1)

We have so far encountered two ways of describing formal languages:

- Deterministic Finite Automata (DFA)

$$(Q, \Sigma, \delta, q_0, F)$$

- Non-deterministic Finite Automata (NFA)

$$(Q, \Sigma, \delta, S, F)$$

COMP2012/G52LAC/Languages and Computation/Lecture 5 - p.27

Syntax of Regular Expressions

1. \emptyset is an RE
2. ϵ is an RE
3. For all $x \in \Sigma$, x is an RE
(Handwriting convention: \underline{x} is an RE)
4. If E and F are REs, so is $E + F$
5. If E and F are REs, so is EF
6. If E is an REs, so is E^*
7. If E is an REs, so is (E)

These are **all** regular expressions.

COMP2012/G52LAC/Languages and Computation/Lecture 5 - p.57

Recap: DFAs and NFAs (2)

Key difference: the type of the transition function:

- **DFA**: $\delta \in Q \times \Sigma \rightarrow Q$
- **NFA**: $\delta \in Q \times \Sigma \rightarrow \mathcal{P}(Q)$

Language of an automaton: the set of all words it accepts.

As DFAs and NFAs are **interconvertible**, these two kinds of automata defines the same **class** of languages.

COMP2012/G52LAC/Languages and Computation/Lecture 5 - p.37

Conventions

- The $*$ -operator has higher precedence than $+$ and sequencing.
E.g.

$$\begin{aligned} ab^* &= a(b^*) \\ a + b^* &= a + (b^*) \end{aligned}$$

- Sequencing has higher precedence than $+$.
E.g.

$$ab + cd = (ab) + (cd)$$
